Annealed Copper Washers

These copper washers are used as a Sealing Washer. The Annealing process makes the material stress free so the contact surfaces are softer, creating a seal as the copper deforms to fit. The copper will also not damage the fastener or housing.

The washer is used in multiple applications like hydraulic connections, automotive and plumbing.

Available in popular BSP and Metric sizes, all are sized to the DIN125, ISO7089 standards.

The copper washer sizes are listed using the ID as reference.

What is Annealing?

The process of annealing copper using heat allows a part of the washer to be softer than the rest. The softer side of the washer is placed against the surface you are tightening to. This allows the washer to properly align to the surface you are placing on and conform to its irregularities. An annealed copper washer is less common and requires more processing during production so is usually slightly more expensive. An annealed copper washer can be identified by its two-tone copper rings.
